# EXAMINATION IN COURSE TKJ 4180 <br> Physical organic chemistry 

LøRDAG 10. DESEMBER 2011,
TIME: KL. 09:00-13:00

Permitted aids :
D
Approved simple calculator Molecular building sets
Ingen trykte eller håndskrevne hjelpemidler er tillatt
This test consists of seven- 7- pages:

## Exercise 1:

Sepp and co-workers have studied the conformation of 2-oxy-substituted tetrahydropyrans. A representative example is shown below.

a. Which conformation is the most stable for the compound shown over, explain the reason(s) behind.

## Exercise 2:

a. The bromination of 3-aryloxycyclohexene gives rise to a mixture of stereoisomers and regioisomeric products. The product composition for $\mathrm{Ar}=$ phenyl is shown. Account for both the stereo and regioselectivity outcome for each of these compounds.

## Exercise 3:

a. The bromination of substituted benzene derivatives shown below is thought to go through an addition-elimination reaction. Assume that the sigma complex is a steady state intermediate. What is the form of the rate expression if the intermediate of the first step goes on to product much faster than it reverts to starting material?

Sigma complex
b. By further investigation of the reaction shown over it was found that there is a rapid equilibrium converting initial $\mathrm{Br}_{2}$ into unreactive $\mathrm{Br}_{3}{ }^{-}$as shown below. What would the the rate expression be if the equilibrium constant for the formation of the tribromide ion is large?

$$
\mathrm{Br}^{-}+\mathrm{Br}_{2}
$$

$\mathrm{Br}_{3}{ }^{-}$

## Exercise 4:

The hydrolysis of $\mathrm{ArCO}_{2} \mathrm{R}(\mathrm{R}=\mathrm{Me}$ and Et$)$ esters carried out in $99.9 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ has been plotted in a Hammet plot. The metyl esters shows a linear plot with $(\rho)=-3.5$. The ethyl ester shows a plot changing from $\rho=-3.5$ to $\rho=2.0$ (left electron donating groups, right electron withdrawing groups)
a. The plot for the ethyl esters has a break of linearity, what does this type of concave upwards deviations normally indicate?
b. What can the rho value ( $\rho$ ) give information about in a Hammett plot?
c. Use the information shown in the Hammet plot to rationalize the mechanism(s) behind hydrolysis of substituted aryl ethyl esters.

## Exercise 5:

a. The Grignard reaction between (S)-2-phenylpropanal and ethylmagnesium bromide is shown below. Predict the stereochemistry of the anticipated main product by using the Crams rule. Name the main product.

b. Steven Ley and co-workers has worked on the total synthesis of the thapsigargin (see below), a family of complex guainolides having $\mathrm{Ca} 2^{+}$modulating effect. One of the steps requires a reaction between the aldehyde shown and the lithium anion of ethyl vinyl ether.Pedict the main product using the Felkin-Ahn model.

Thapsigargin

## Exercise 6:

a. The acetolysis of cyclohex-3-enyl 4-methylbenzenesulfonate results in the formation of the three products shown below: Show the mechanism for the formation of these products.

b. The acetolyses of enantiomeric enriched exo-2-norbornyl brosylate gives rise to completely racemic exo-acetate. Endo-2-norbornyl brosylate gives 93\% racemisation. The exo form also reacts 350 times faster than the endo form. Account for both the unusual stereoselectivity and the rate difference.

## Exercise 7:

The hydrolysis of several substituted aryl acetals in acidic medium has been investigated and is shown below.

| $\underline{R}$ | $\underline{\sigma}$ | $\underline{\text { Rate }}$ |
| :--- | ---: | :---: |
| 4-Dimethylamino | $-0,63$ | $1,47 \mathrm{E}+05$ |
| 4-Amino | $-0,57$ | $4,91 \mathrm{E}+04$ |
| 4-Hydroxy | $-0,37$ | $2,83 \mathrm{E}+04$ |
| 4-Methoxy | $-0,268$ | $9,40 \mathrm{E}+03$ |
| 4-Methyl | $-0,17$ | $2,09 \mathrm{E}+03$ |
| H | 0 | $9,56 \mathrm{E}+02$ |
| 3-Methoxy | 0,115 | $4,53 \mathrm{E}+02$ |
| 4-Chloro | 0,227 | $4,07 \mathrm{E}+02$ |
| 3-Bromo | 0,391 | $1,56 \mathrm{E}+02$ |

a. Draw a Hammet plot using the susbtituent constant $\sigma$ and the rate data. Use the plot to find the slope (rho value).
b. Write the mechanism for acid catalysed hydrolysis of acetals and indicate the rate limiting step. Assume that hydrolysis of the hemiacetals are faster than hydrolysis of the acetals.
c. Does the Hammet plot agree with what you have proposed as the rate limiting step in question b?
