**Life cycle:** All development stages of an item of equipment or function, from when the study commences up to and including disposal

**Life cycle cost (LCC):** Discounted cumulative total of all costs incurred by a specified function or item of equipment over its life cycle

**Life cycle costing:** Process of economic analysis to assess the life cycle cost of a specified function or item of equipment over its life cycle or a portion thereof

Life cycle cost is sometimes called “Total ownership cost”

ISO 15663 and IEC 60300-3-3

Do never be tempted by the attraction of an initially cheap system! There are usually more costs:

- Cost of low productivity
- Cost of low reliability
- Cost of lost production
- High logistics cost
- High maintenance cost
- High operating cost

Poisson process

LCC Process

An investment of  $PV$  (present value) will increase to  $FV(1)$  (with interest) after one year. The *interest rate*  $r$  in year no. 1 is then:

$$r = \frac{FV(1) - PV}{PV}$$

such that

$$FV(1) = PV \cdot (1 + r)$$

After 2 years the future value, with constant interest rate, is

$$FV(2) = (PV \cdot (1 + r)) \cdot (1 + r) = PV \cdot (1 + r)^2$$

and after  $t$  years the future value  $FV(t)$  is

$$FV(t) = PV \cdot (1 + r)^t$$

Note that  $PV = FV(0)$

Horizon

Equivalence

Poisson process

LCC Process

Discounting is a means of comparing costs and benefits that occur at different points of time.

If we get the value  $FV(1)$  after one year and this corresponds to the present value  $PV$ , then the annual *discount rate* is

$$d = \frac{FV(1) - PV}{FV(1)}$$

The present value,  $PV$ , of an investment  $FV(1)$  in year 1 is therefore:

$$PV = FV(1) \cdot (1 - d)$$

and the present value  $PV$ , of an investment  $FV(t)$  in year  $t$  is

$$PV = FV(t) \cdot (1 - d)^t$$

# Discounting

Interest rate

Criticism

Horizon

Equivalence

Poisson process

LCC Process

We note that the discount rate is different from the interest rate, but that they have the following relationship:

$$d = \frac{r}{1 + r} \quad r = \frac{d}{1 - d}$$

If the interest rate is  $r = 0.05$  the discount rate is  $d \approx 0.0476$ . In many cases, we do not distinguish between the two rates and use the same value for both.

The discount rate is “the rate of interest reflecting the investor’s time value of money.” Basically, it is the interest rate that would make an investor indifferent as to whether he received a payment now or a greater payment some time in the future.

# Limit value

Interest

**Discount**

Interest rate

Criticism

Horizon

Equivalence

Poisson process

LCC Process

Assume now that interest is paid and added, not once a year, but  $n$  times a year. Since the interest rate is constant, the value after the first period is (the interest rate is given per year):

$$FV(1) = PV \cdot \left(1 + \frac{r}{n}\right)^n$$

After  $t$  years this becomes

$$FV(t) = PV \cdot \left(1 + \frac{r}{n}\right)^{nt}$$

If we let  $n \rightarrow \infty$

$$FV(t) = \lim_{n \rightarrow \infty} PV \cdot \left(1 + \frac{r}{n}\right)^{nt} = PV \cdot e^{rt}$$

Note that this approach will not give exactly the same answer as the previous approach since we get “interest of interest”

## Limit values – Example

Interest

**Discount**

Interest rate

Criticism

Horizon

Equivalence

Poisson process

LCC Process

Assume that we invest 100 Euros at time  $t = 0$  with interest rate 5%. The value after one year is then

$$FV(1) = 100 \cdot (1 + 0.05) = 105$$

If we split the interval into  $n = 6$  and hence add interest every second month, the value after one year is

$$FV(1) = 100 \cdot \left(1 + \frac{0.05}{6}\right)^6 \approx 105.11$$

If we approximate by using the exponential function we get

$$FV(1) = 100 \cdot e^{0.05} \approx 105.13$$

# Approximation

Introduction

Definition

Objectives

Applications

Perspectives

Initial cost

Standards

Life phases

Interest

**Discount**

Interest rate

Criticism

Horizon

Equivalence

Poisson process

LCC Process

This means that we approximately have

$$PV = FV(t) \cdot e^{-rt}$$

or, more correctly: the interest rate  $r$  should be replaced by the discount rate  $d$ .

---

On a previous slide we found that  $PV = FV(t) \cdot (1 - r)^t$ . Since we know that the exponential function can be written as a Maclaurin series,  $e^{-r} = \sum_{k=0}^{\infty} \frac{(-r)^k}{k!}$  and since  $r$  is a small number, we have that  $e^{-r} \approx 1 - r$ , and we can therefore deduce the above result by using approximation to the exponential function.

# Instantaneous interest rate

Introduction

Definition

Objectives

Applications

Perspectives

Initial cost

Standards

Life phases

Interest

Discount

**Interest rate**

Criticism

Horizon

Equivalence

Poisson process

LCC Process

Let  $i(t)$  be the accumulated interest of PV at time  $t$ . We then have that  $FV(t) = PV + i(t)$ . The rate of change of the accumulated interest at time  $t$  (if  $FV(t)$  is differentiable) is

$$\lim_{\Delta t \rightarrow 0} \frac{FV(t + \Delta t) - FV(t)}{\Delta t} = \frac{dFV(t)}{dt}$$

The annual interest rate in the year  $(t, t + 1)$  is (assume now that  $\Delta t = 1$ ):

$$r_1(t) = \frac{1}{FV(t)} \cdot \frac{FV(t + \Delta t) - FV(t)}{\Delta t}$$

By letting  $\Delta t \rightarrow 0$ , we get the *instantaneous interest rate*

$$r(t) = \frac{1}{FV(t)} \cdot \frac{dFV(t)}{dt}$$

# Future value

Introduction

Definition

Objectives

Applications

Perspectives

Initial cost

Standards

Life phases

Interest

Discount

**Interest rate**

Criticism

Horizon

Equivalence

Poisson process

LCC Process

If we “know” the interest rate as a function of time, we may now find  $FV(t)$  from the differential equation

$$FV'(t) = r(t) \cdot FV(t) \quad \Rightarrow \quad \frac{FV'(t)}{FV(t)} = \frac{d}{dt} \ln FV(t) = r(t)$$

Since we know  $FV(0) = PV$ , the solution will be

$$FV(t) = PV \cdot e^{\int_0^t r(\tau) d\tau}$$

and the present value of an investment/loss at time  $t$  is

$$PV = FV(t) \cdot e^{-\int_0^t r(\tau) d\tau}$$

(In the last expression we should use the discount rate instead of the interest rate)

# Criticism of the present value approach

Initial cost

Standards

Life phases

Interest

Discount

Interest rate

**Criticism**

Horizon

Equivalence

Poisson process

LCC Process

The approach of discounting future costs has been criticized when used for environmental impacts and accidents with a very high consequence and a low frequency. An accident that occurs 100 years from now and implies a cost of, e.g., 100 million Euros, will – with a discount rate of 5% – have a present value of approximately 592 000 Euros. The situation is much worse for extreme accidents with a very, very low frequency.

If we use present value arguments to decide whether or not to install equipment to prevent major accidents, the world will not be a very safe place to live!

# Financing horizon

Introduction

Definition

Perspectives

Initial cost

Standards

Life phases

Interest

Discount

Interest rate

Criticism

**Horizon**

Equivalence

Poisson process

LCC Process

Let  $\tau$  denote the financing horizon of a prospect. For an offshore oil and gas installation the financing horizon is often around 20 years. For infrastructure facilities, the financing horizon lies typically at the end of the useful service life or design life – in the order of 50–100 years.

Niels Lind (2007) has proposed an alternative discounting scheme to avoid the present value problem for accidents with a low frequency (see previous slide). He proposes to let the discount/interest rate  $r(t)$  be equal to 0 after the financing horizon. This means that an accident that occurs at time  $t$  will have the same present value for all  $t \geq \tau$ .

In some guidelines the financial horizon is called “study period”

**Poisson process**

LCC Process

Consider a specific type of accidents. We assume that the occurrence of accidents may be modeled as a homogeneous Poisson process with rate  $\lambda$ . The number  $N(t)$  of accidents in a time interval of length  $t$  then has the probability distribution

$$\Pr(N(t) = n) = \frac{(\lambda t)^n}{n!} e^{-\lambda t} \quad \text{for } n = 0, 1, 2, \dots$$

The mean number of accidents in an interval of length  $t$  is  $E(N(t)) = \lambda t$ . The total cost related to an accident is denoted  $C$ . The mean accident cost in year no.  $i$  is therefore ( $t = 1$ ),  $C\lambda$ , and the present value of this accident is  $PV_i = C\lambda(1 - d)^i$ , where  $d$  is the discount rate.

Poisson process

LCC Process

Assume that the total life of the system is  $n$  years. The present value of the total mean accident cost is then

$$PV = \sum_{i=1}^n PV_i = C\lambda \sum_{i=1}^n (1-d)^i = C\lambda \frac{(1-d) - (1-d)^{n+1}}{d}$$

Assume now that the financial horizon of the system is  $m < n$  years. By following Niels Lind's approach, the present value of the total mean accident cost is

$$\widetilde{PV} = \sum_{i=1}^n PV_i = C\lambda \frac{(1-d) - (1-d)^{m+1}}{d} + (n-m)(1-d)^m \cdot C\lambda$$

With  $n = 40$ ,  $m = 20$  and  $d = 5\%$ , the “difference” between the two approaches is

$$\widetilde{PV}/PV \approx 1.17$$
