# *Analyzing the Robustness of Certain Trust*

Sebastian Ries, Andreas Heinemann

# Overview

- Motivation
  - What's the goal?
- Approach
  - CertainTrust: Deriving trustworthiness from evidence
- Robust integration of recommendations
  - Filtering, weighting & limiting
- Evaluation
  - What are the results?
- Conclusions
  - What we have achieved!

# Motivation

# Scenario: Collaborative Information Dissemination

Alice

Music Search:

<\Title=  
"Trust Me" >

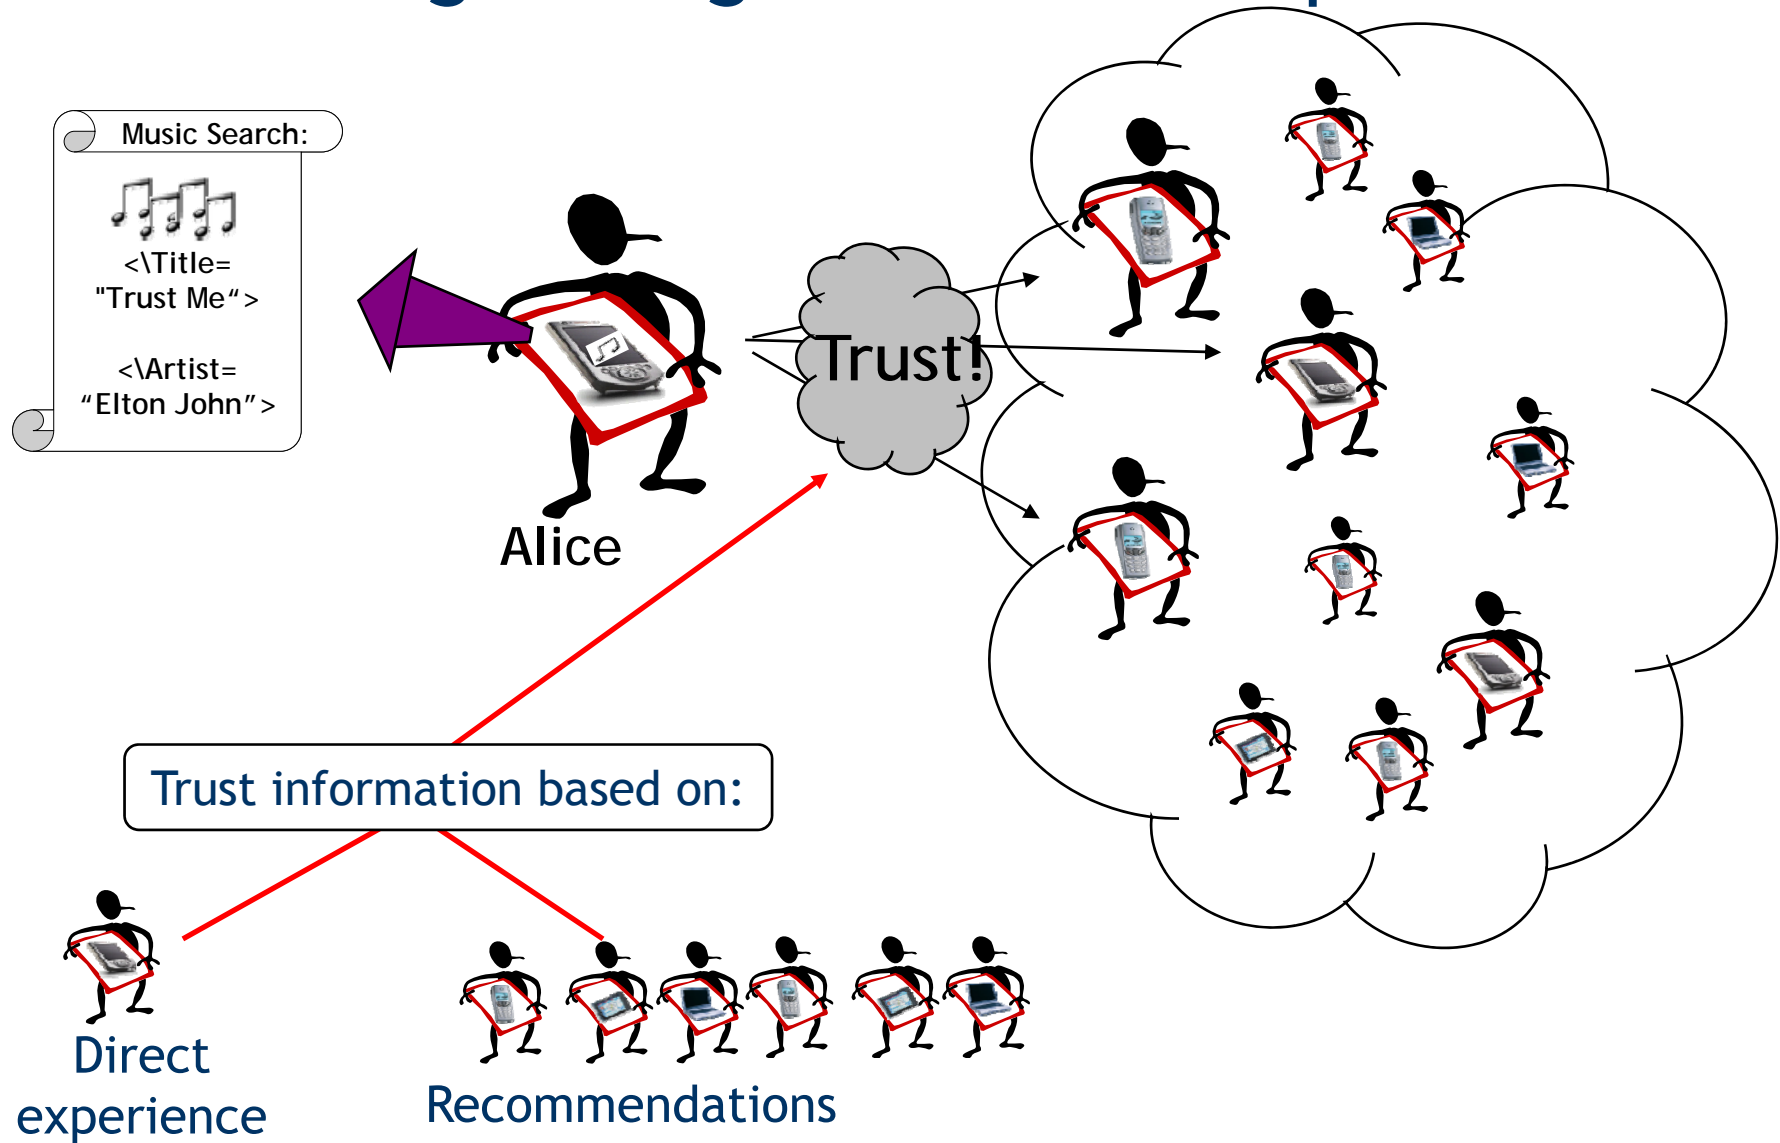

<\Artist=  
"Elton John" >

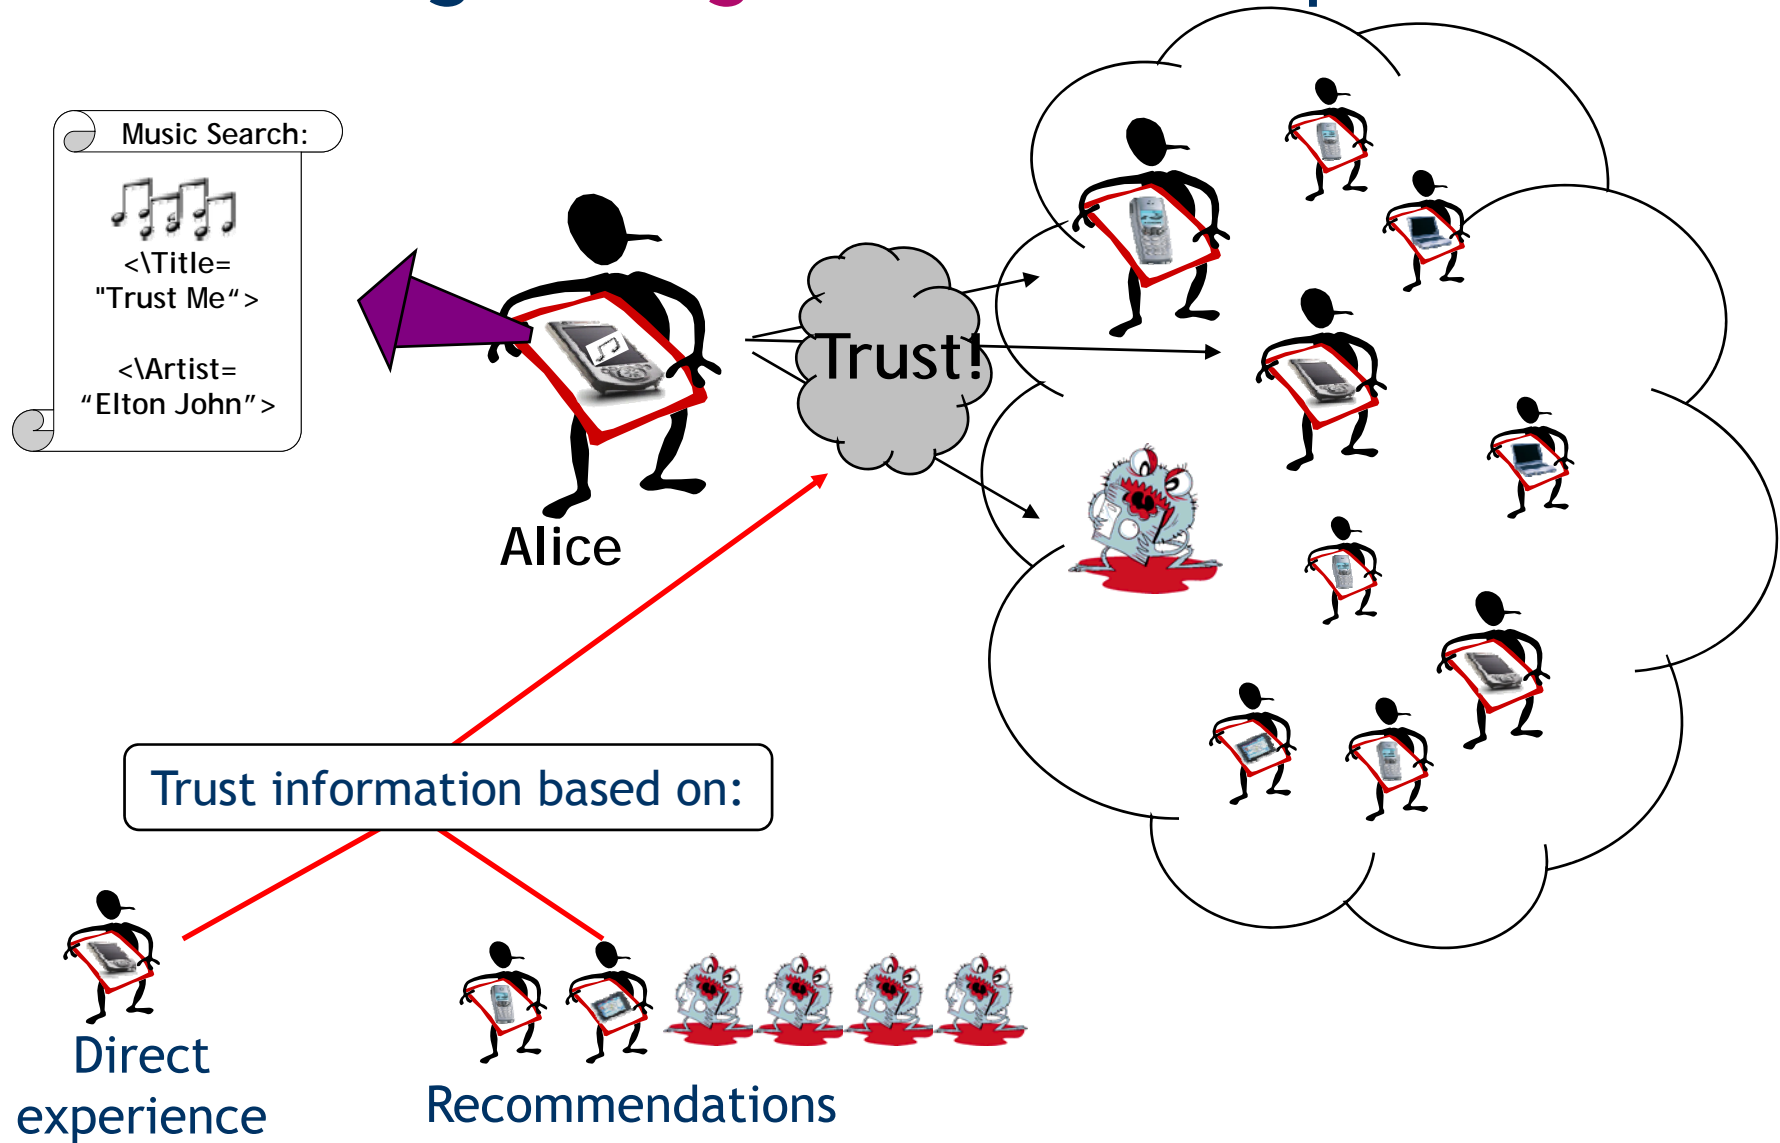

# The crowd in front of the stadium

# Finding the right interaction partner

# Finding the right interaction partner

## Beyond this simple scenario ...

- **Goal:** Improving the quality of interactions using trust as a basis for decision making
  - **Sub goal:** Estimating the trustworthiness of an entity
- **Approach: History based trust establishment** using
  - Direct experience from past interactions
  - Indirect Experience: Recommendations
  - User knowledge

# Approach

# Challenge

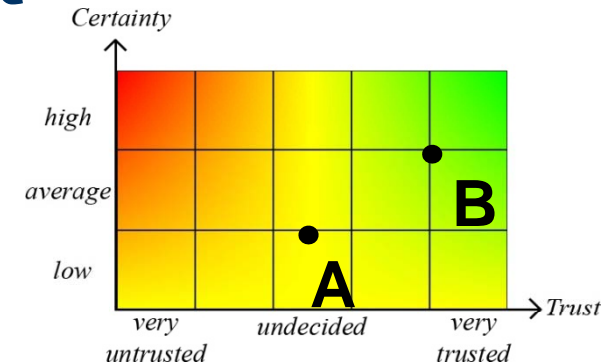

- Definition: **Trust** (or, symmetrically, distrust) is a particular level of the **subjective probability** ... [Gambetta]
- Estimating the **trustworthiness** of an entity
  - In the context of providing a service / interaction (e.g., file exchange)
    - Estimating the probability for providing a interaction with a positive outcome
  - In the context of recommendations
    - Estimating the probability for providing accurate recommendations

Both is done based on experience linked to past interactions

# CertainTrust

- Experience (evidence):  
# positive / negative evidence
  - Main parameters in the model:
    - **Trust value (t):**
      - Reflects the outcome of the past interactions
    - **Certainty (c):**
      - Increases with number of collected evidence
      - Limit for the collected evidence is **maxExp**
    - **Initial Expectation (f):**
      - The expectation about a positive outcome in an interaction with an unknown entity
- ⇒ **Expectation Value (Estimated Trustworthiness) (E):**
- $E = t*c + (1-c) * f$  (alternatively bayesian mean)
  - Subjective probability for positive outcome in the next interaction

# How to choose the *initial expectation* $f$ ?

- **Moderate approach:**  $f = 0.5$ 
  - Expectation value for an unknown entity is 0.5 (as assumed in most State-of-the-Art approaches)
- Selected alternatives: optimistic ( $f=1$ ), pessimistic ( $f=0$ )
  - May also be appropriate! E.g.,  $f=1$  (or close to 1) in very friendly environments (or populations)
- Be aware this assumption may be wrong!
- Solution: **Dynamically update  $f$  based on the experienced behavior over all encountered entities in the context!**
  - Initial: value for  $f = 0.5$
  - Learning based on encountered entities:
    - With positive experience =>  $f$  shifts towards 1
    - With negative experience =>  $f$  shifts towards 0

# Robust integration of recommendations

# Challenge

Overcome the problem  
that direct experience may be rare ...

... by aggregating ...

- Direct experience
  - Incl. typical behavior of the community
- Recommendations

... in the face of lying recommenders

# Approaches for robust integration of recommendations

- A recommendation is a tuple of pos./neg. exp:  
 $\text{rec}_B^A = (\#\text{pos.}, \#\text{neg.}) - [A\text{'s direct experience with } B]$
- Filtering of recommendations
  - Consider only recommenders which provided mostly accurate recommendations
- Weighting of recommendations (Discounting)
  - Limit the number of evidence each entity may provide
  - Weight recommendations according to the trustworthiness of the recommender in the context providing accurate recommendations (using the right type of trust for recommenders!!!)
- Focus on direct experience and the best recommenders
  - Limit the number of evidence which is considered per interaction candidate

# Achievements

- Gaining trust by recommendations is based on the most trusted recommenders:
    - Recommendations by unknown / little trusted recommenders have only small impact (if any)
    - Good resistance to attacks based on misleading recommendations
  - Gaining direct trust requires ...
    - for interactors: providing good interactions
    - for recommenders: providing accurate recommendations
- ⇒ Attacks are connected to the costs of first providing good interactions or accurate recommendations

# Evaluation

# Evaluation

- Scenario: Collaboration in Opportunistic Networks
  - Users moving around with their personal devices sharing files with entities in proximity (distributed system)
  - Mobility model based on traces of the Reality Mining Project
    - About 100 participants, tracking based on mobile phones
    - Entities are assumed to be close to each other, if they are connected to the same mobile phone cell tower with a 15 min interval
  - Goal of an entity:  
Having as many interactions with positive outcome as possible!

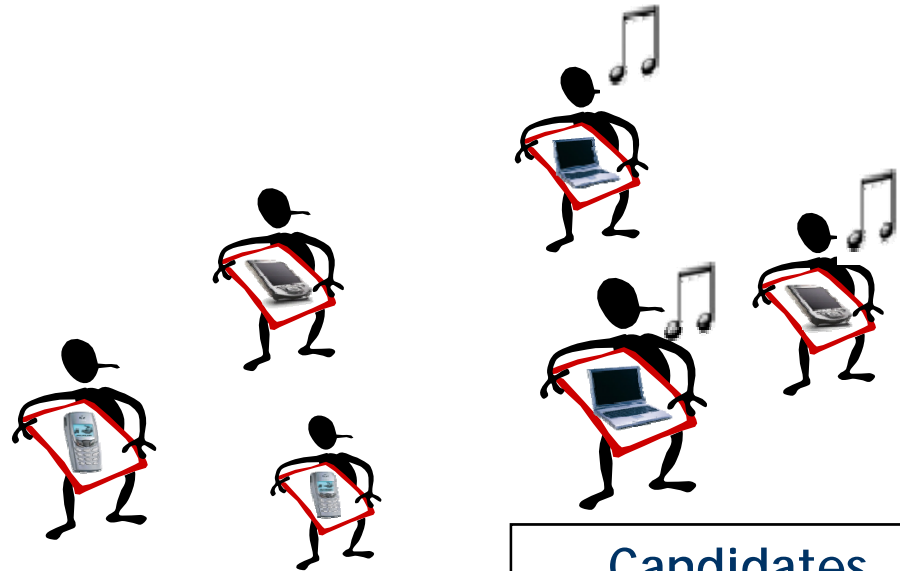

# Scenario - Select best interaction partner

Alice -  
Initiator

Candidates

Recommenders

Selection based on direct experience & recommendations

Initiator **MUST** interact with best candidate

# Behavior of entities

- Possible user behavior derived from system model

Basic entity behaviors		Recommendation behavior	
		+	-
Interaction behavior	+	honest (h)	selfish (s)
	-	malicious (m)	worst (w)

- Two settings modeling the stability of the interaction behavior
  - deterministic:  
 $P(\text{"entity adheres to assigned interaction behavior"}) = 1$
  - **probabilistic**:  
 $P(\text{"entity adheres to assigned interaction behavior"}) \in_U [0.5;1]$

# Populations

- 15 canonically derived populations:
  - h, m, s, w, hm, hs, hw, ..., hmsw
- Example:
  - Population h: all entities are honest
  - Population hm: 50% of entities are honest, 50% of entities are malicious
  - ...
  - Population hmsw: 25% of entities are {honest, malicious, selfish, worst}

# Baselines

- Random selection - (Const05)
- Distributed Variants of the BetaRepSys
  - Beta(\_Simple)
    - No weighting of recommendations
  - Beta\_D(iscounting)
    - Weighting of recommendations is based on the assumption that an entity's behavior as interactor is equal to its behavior as recommender
- Perfect Model
  - Doing the selection based on the knowledge of the true probabilities for positive outcomes

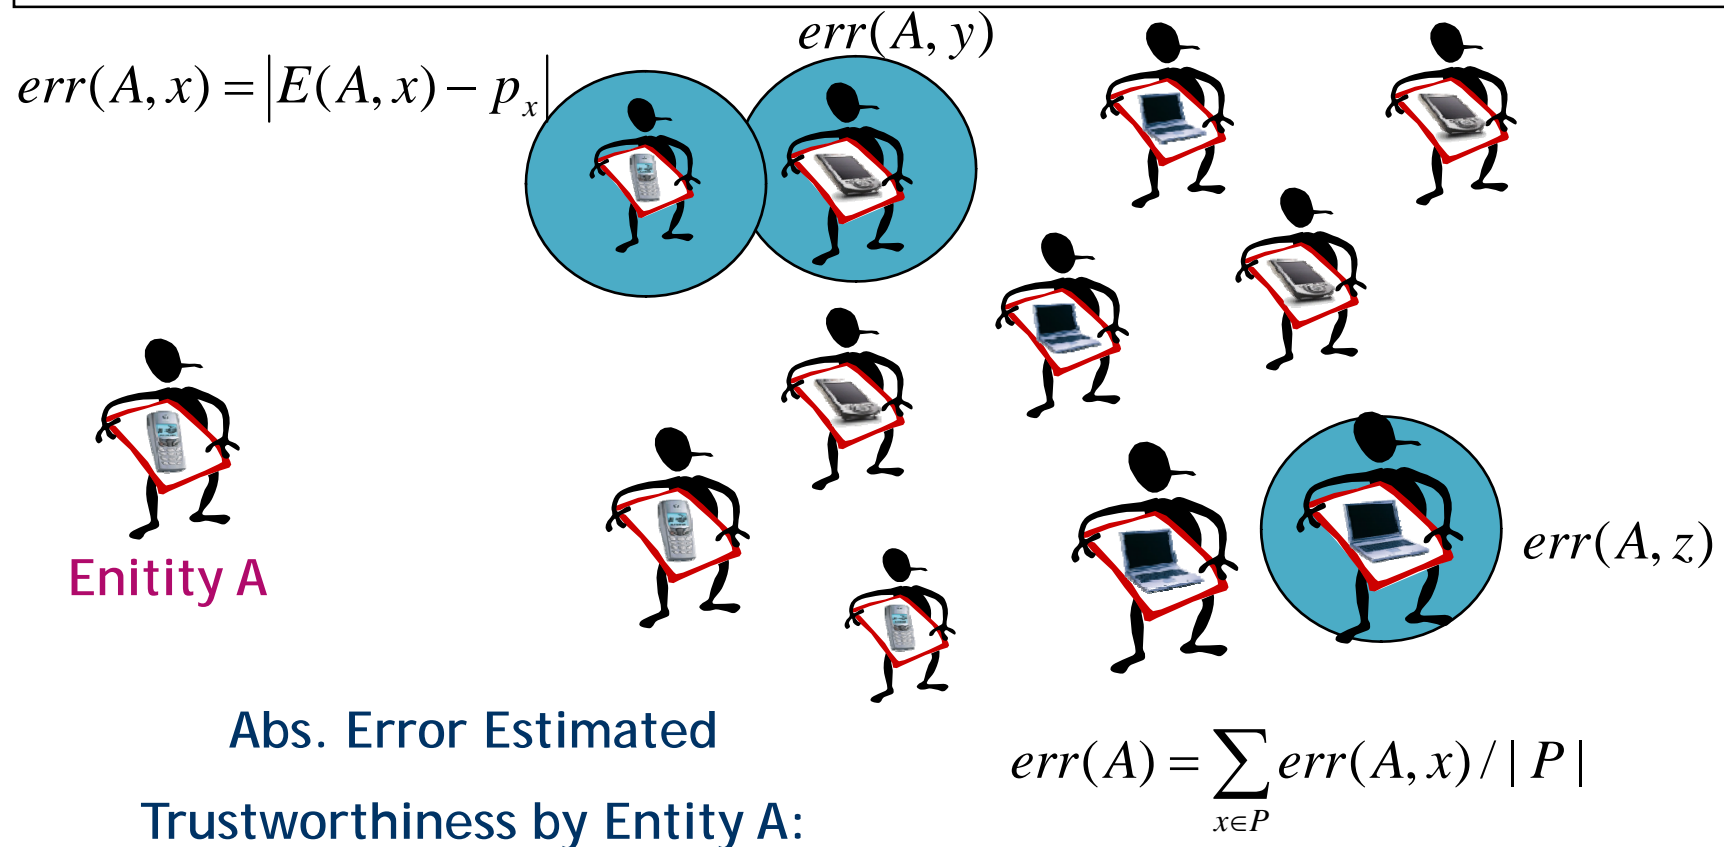

# Evaluation Metrics

# Error in Estimating the Trustworthiness

At the beginning of the simulation each entity is assigned a probability  $p$  for providing a "good interaction" (derived from the behavior).

The calculated trustworthiness is an estimate for this parameter.

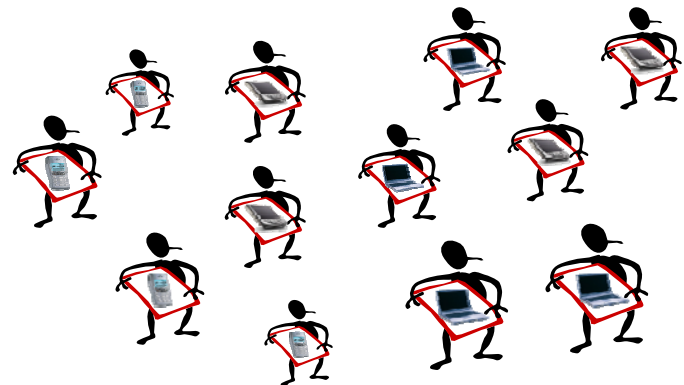

# Avg. Abs. Error in Estimating the Trustworthiness for all entities =

( Abs. Error Estimated Trustworthiness by Entity 1

+ Abs. Error Estimated Trustworthiness by Entity 2

...

+ Abs. Error Estimated Trustworthiness by Entity n ) / n

# Results (trustworthiness)

Avg. Error in Estimating the Trustworthiness (stability in [0.5;1])

# Results (trustworthiness)

Avg. Error in Estimating the Trustworthiness (stability in [0.5;1])

# Results (trustworthiness)

Avg. Error in Estimating the Trustworthiness (stability in [0.5;1])

# Results (trustworthiness)

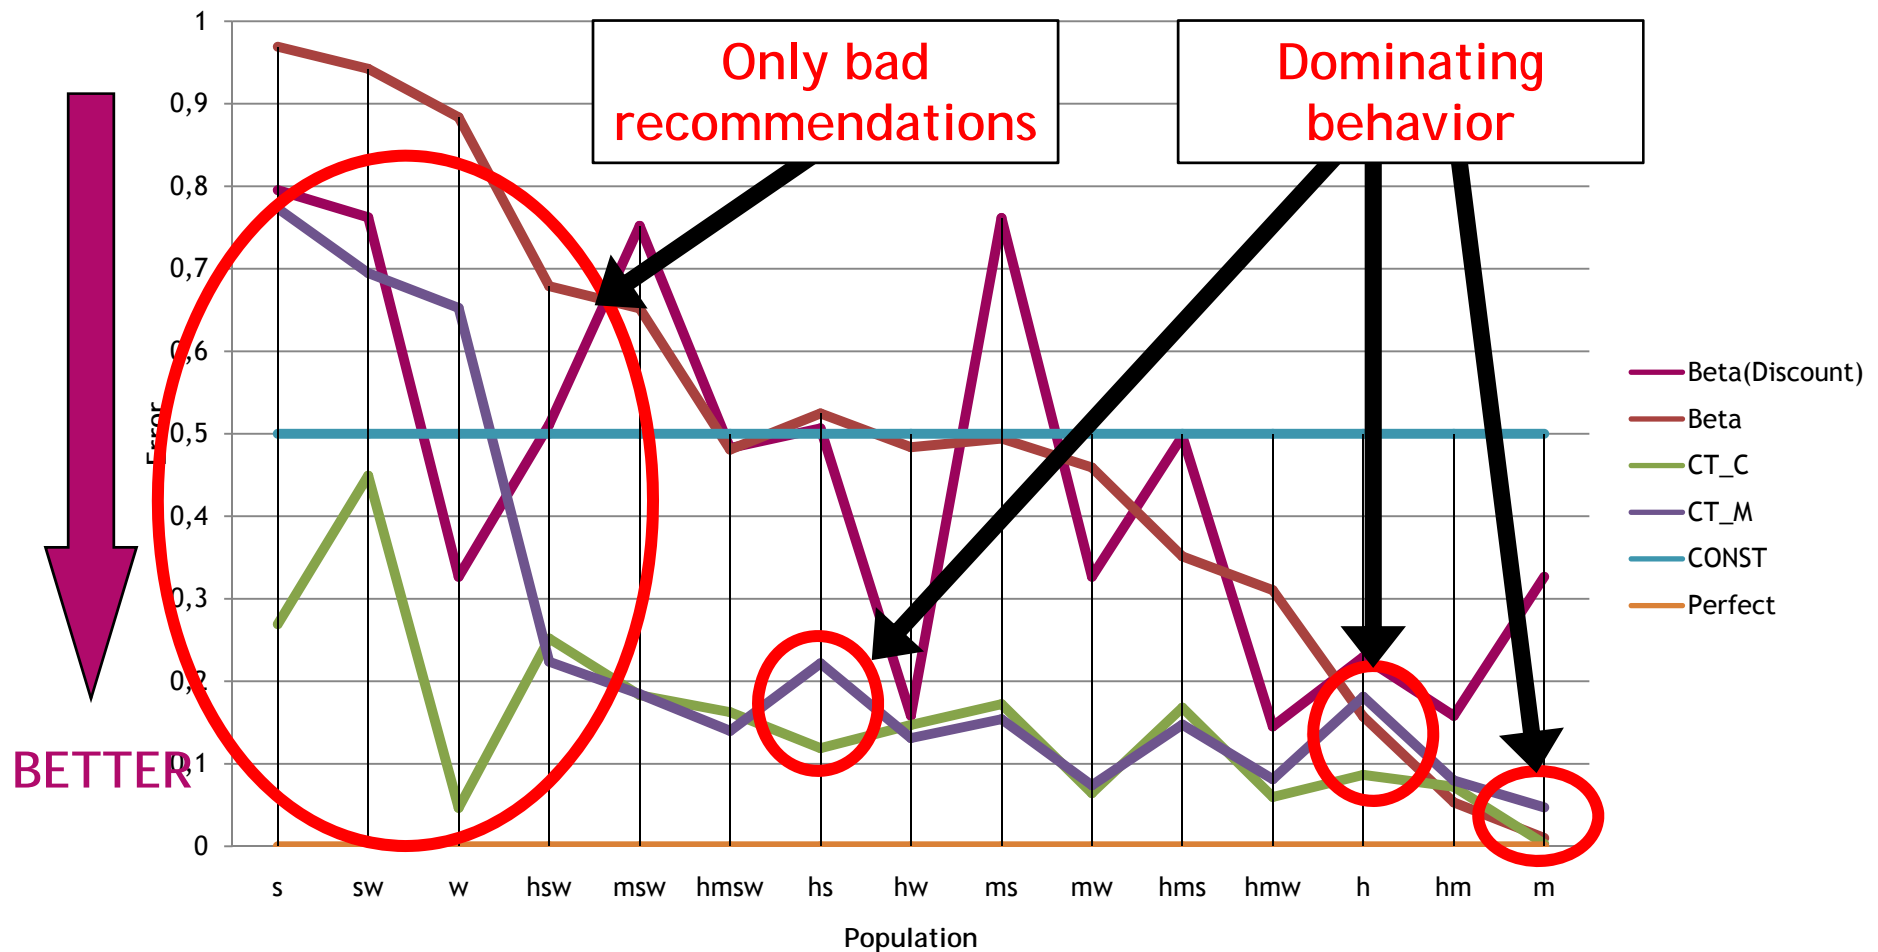

Avg. Error in Estimating the Trustworthiness (stability in [0.5;1])

# Results (trustworthiness - stability = 1)

Avg. Error in Estimating the Trustworthiness (stability = 1)

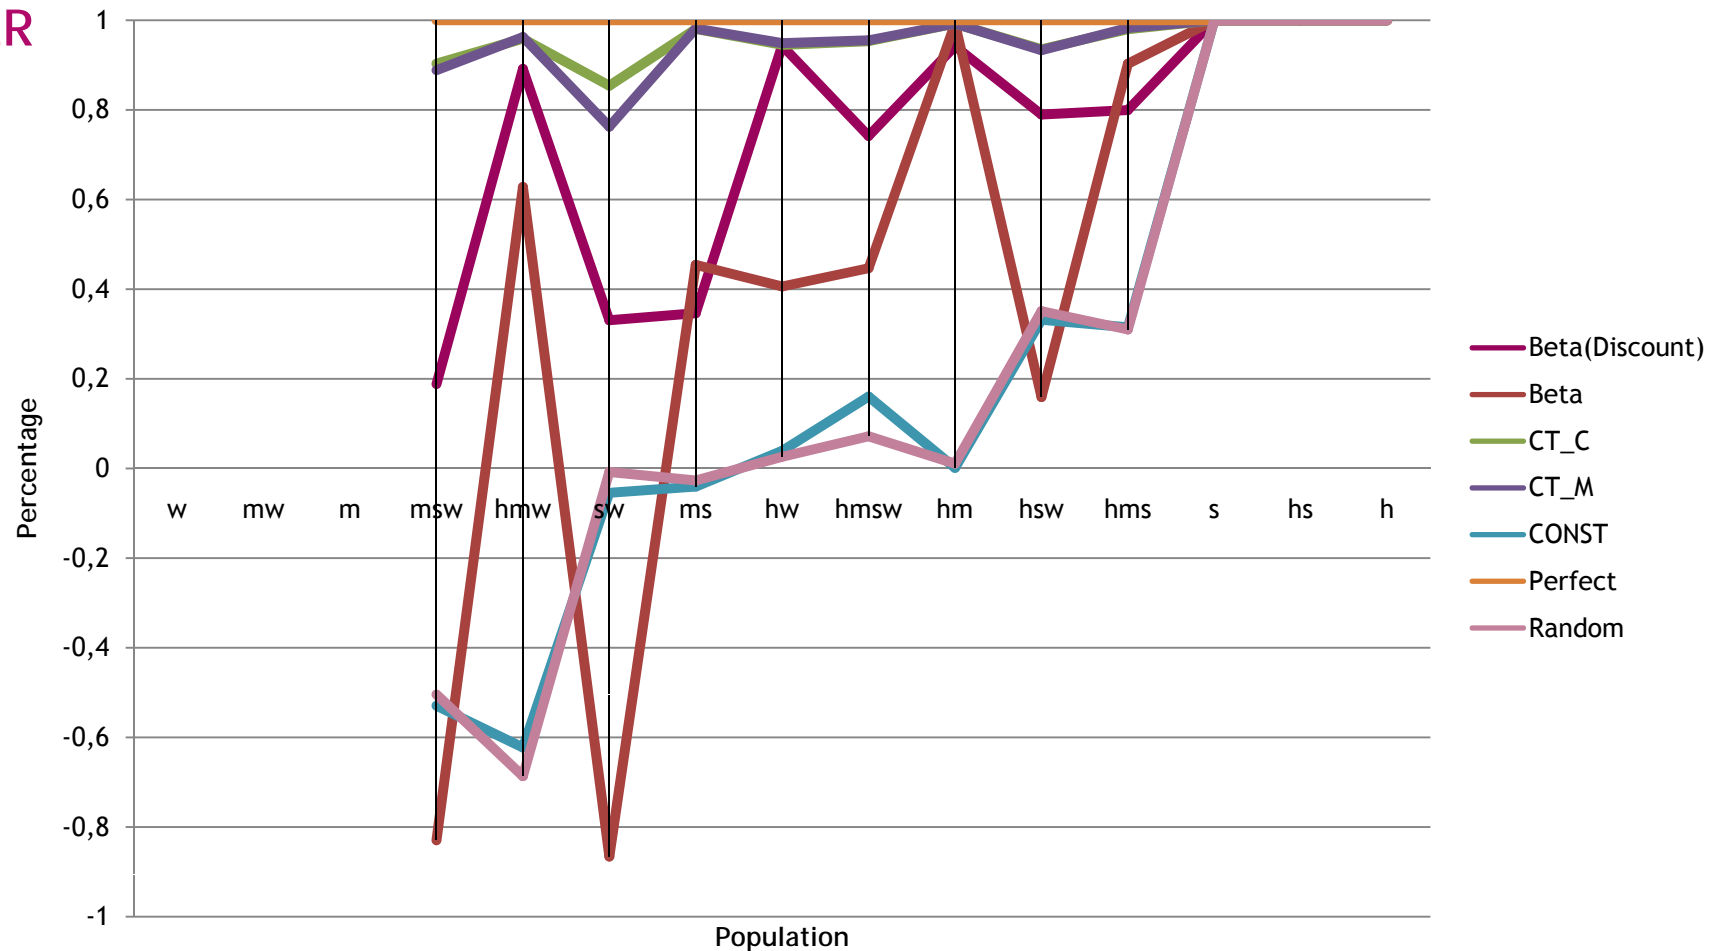

# Results (acc. sum - stability = 1)

Avg. Percentage Acc. Sum of Feedback (stability = 1)

BETTER

# Interpretation of the Results

- Evaluated the model in a distributed scenario
  - Over a canonical set of populations
    - Showing the wide range of applicability of CertainTrust
  - With good results
    - Percentage acc. sum beyond 80% in 18 of 24 populations
    - Estimated trustworthiness allows to approximate probability of positive outcome
- The ideas should not be measured by the absolute numbers, but by the relative improvement!

# Conclusions

- Provided a trust model
  - Allowing for dynamically updating the initial expectation about unknown entities
  - With robust filtering & trust update techniques
    - Limit influence of unknown/little trusted recommender
    - Using the right type of trust for weighting recommendations
    - Gaining direct trust is strictly linked to interactions
- Improved the overall quality of interactions
- Yet, enhancing robustness towards false recommendations and Sybil attacks beyond the simulated scenario

Thank you!
