## Exercise 1 (40 points)

In their paper "A nation of immigrants: Assimilation and economic outcomes in the age of mass migration" published in the Journal of Political Economy in 2014, Abramitzky, Boustan, and Eriksson study the assimilation of European immigrants in the United States labor market during 1850-1913. In this period almost thirty million, mostly European, immigrants moved to the US. The common view among scholars has been that European immigrants held substantially lower-paid occupations than natives upon first arrival, but that they converged with the native born after spending some time in the US. The paper provides new light to this issue.

The authors construct two datasets. They start by obtaining three random samples of migrants and natives from the United States census of the population, one for year 1900, one for the year 1910 and finally one for the year 1920. For the second dataset, they build a panel dataset in the following way. They start from the random sample of natives and migrants they have for 1900 and then they search these individuals by their name, surname and age in the 1910 Census and, again, in the 1920 Census. In doing this exercise, their matching rate is about $25 \%$. In other words the authors are able to follow $25 \%$ of the original 1900 sample over time.

Next, they estimate different versions of the following model:

$$
\begin{align*}
\text { Earnings }_{i t} & =\beta_{0}+\beta_{1} Y 0_{-} 5_{i t}+\beta_{2} Y 6 \_10_{i t}+\beta_{3} Y 11 \_20_{i t}+\beta_{4} Y 21 \_30_{i t}+\beta_{5} Y 30_{i t}+  \tag{1}\\
& +\beta_{6} \text { age }_{i t}+\beta_{7} \text { age }_{i t}^{2}+\beta_{8} \text { age }_{i t}^{3}+\beta_{8} \text { age }_{i t}^{4}+\beta_{9} \text { after } 1890+\theta_{t}+\alpha_{j}+a_{i}+u_{i t}
\end{align*}
$$

In equation (1), $i$ indicates individuals and $t$ time (1900, 1910, 1920). Earnings ${ }_{i t}$ measures the earnings of individuals in 2010 dollars; $Y 0 \_5$ is an indicator that equals one if the migrant has spent in the US zero to 5 years and zero otherwise, Y6_10 is an indicator that equals one if the migrant has spent in the US 6 to 10 years and zero otherwise, and so on, until $Y 30$, which is an indicator that equals one if the migrant has spent in the US more than 30 years and zero otherwise. The omitted category here is being a US born. age $i_{t}$ indicates the age of the individual, which appears as a fourth-degree polynomial; after1890 is an indicator that equals one if the migrant arrived after 1890. Finally, $\theta_{t}$ indicates Census year fixed effects, $\alpha_{j}$ indicates country of birth fixed effects and $a_{i}$ indicates individual fixed effects.

The results from their analysis are reported in Table 1 on page 2. In column (1) and (2), the authors use the pooled data, and the model is estimated by OLS. In column (3), the authors use the panel data and the model is estimated using a fixed-effect estimator.
(a) (5 points) Interpret the coefficients for the years 0 to 20 reported in column (1). What can you conclude about the earnings profile of the immigrants?
(b) (10 points) Focus only on the results reported in column (1) and (2). Why does the immigrantnative earnings gap in the first five years since arrival $\left(\hat{\beta}_{1}\right)$ shrink?
(c) (10 points) A young referee suggests that part of the reasons that explain different assimilation profiles could be permanent differences in earnings between immigrant women and other groups, i.e. discrimination against immigrant women. The referee therefore proposes to include in the model of column (3) an indicator for being a female migrant. Provide a brief comment to this proposal.
(d) (15 points) The abstract of the paper reads along these lines: "Prior cross-sectional work finds that immigrants initially held lower-paid occupations than natives but converged over time. In newly-assembled panel data, we show that, in fact, the average immigrant did not face a substantial earnings penalty upon first arrival and experienced earnings growth at the same rate as natives. Cross-sectional patterns are driven by biases from declining arrival cohort quality and departures of negatively-selected return migrants." Discuss whether the conclusion that immigrant did not face substantial earnings penalties upon arrival could be questioned. Next, discuss whether cross-sectional patterns could be explained by other reasons besides cohort quality. Remember to base your statements on the concepts learned in class.

Table 1: Age-earnings profile for natives and foreignborn, 1900-1920

|  | POLS | POLS | FE |
| :--- | :---: | :---: | :---: |
|  | Earnings | Earnings | Earnings |
|  | $(1)$ | $(2)$ | $(3)$ |

| N | 205,458 | 205,458 | 65,804 |

Source: selected and modified results from Table 4, Abramitzky et al. (2014), p. 484.
Earnings are measured in 2010 dollars. See text for explanation of the other variables and of the different samples.

## Exercise 2 (40 points)

Romer (1993) proposes theoretical models of inflation that imply that more open countries should have lower inflation rates. His empirical analysis explains average annual inflation rates (since 1973) in terms of the average share of imports in gross domestic product since 1973-which is his measure of openness. While Romer does not specify both equations in a simultaneous system, he has in mind a two-equation system:

$$
\begin{align*}
\text { inf } & =\beta_{10}+\alpha_{1} \text { open }+\beta_{11} \text { lpcinc }+\beta_{12} \text { oil }+u_{1}  \tag{1}\\
\text { open } & =\beta_{20}+\alpha_{2} \text { inf }+\beta_{21} \text { lpcinc }+\beta_{22} \text { lland }+u_{2}, \tag{2}
\end{align*}
$$

where inf measures the annual inflation rate, open measures imports as \% of GDP, lpcinc is the log of 1980 per capita income measured in U.S. dollars, lland is the log of land area of the country measured in square miles and oil is a dummy variable that takes value of one if the country is an oil producer and zero otherwise.

The do-file of the analysis is reported on page 5 and the relative log-file starts on page 6 .
(a) (5 points) Consider first the analysis reported on line 17-21 of the do-file. Using a $5 \%$ significance level, test for heteroskedasticity.
(b) (10 points) Discuss under which conditions the estimator reported on line 27 and 28 of the do-file can identify the parameters $\alpha_{1}$ and $\alpha_{2}$. If needed, base your answer on appropriate tests.
(c) (5 points) A commentator suggests to use land in levels, rather than in logs (lland), as an instrument for open. Provide at least two strategies based on which to decide which regressor to include.
(d) (10 points) How would you test whether the OLS and IV estimates on the equation for open are statistically different?
(e) (10 points) Explain whether you think the estimator used on line 27 of the do-file for $\inf$ is consistent and efficient.

## Exercise 3 (20 points)

In their article "Do police reduce crime? Estimates using the allocation of police forces after a terrorist attack." published in the American Economic Review (2004), Di Tella and Schargrodsky wirte: "An important challenge in the crime literature is to isolate causal effects of police on crime. Following a terrorist attack on the main Jewish center in Buenos Aires, Argentina, in July 1994, all Jewish institutions received police protection. Thus, this hideous event induced a geographical allocation of police forces that can be presumed exogenous in a crime regression. Using data on the location of car thefts and police forces before and after the attack, we find a large deterrent effect of observable police on crime".
(a) (10 points) Let CarTheft ${ }_{i t}$ indicate the number of car thefts in location $i$ at time $t$, and New Police $_{i t}$ the number of policemen allocated to location $i$ at time $t$. Explain which model you think the authors are using to pin down the causal effect of police on crime.
(b) (10 points) Interpret the coefficient(s) you have mentioned at point (a).
